

controller_usage_demonstration_new

June 29, 2017

This Jupyter Notebook demonstrates how to enable the GridBallast controllers for a load (a water heater or a zip load) in GridLAB-D.

We have four controllers which can be applied on each load, namely

- lock mode controller
- frequency controller
- voltage controller
- thermostat controller [optional for zip load]

Lock mode controller can force the load to be either ON/OFF during certain period, by specifying **enable_lock** and **lock_STATUS** variables in .glm file. **enable_lock** refers to a schedule file indicating when the lock mode is forced, **lock_STATUS** refers to another schedule file indicating whether the load to be ON or OFF.

```
schedule temp_lock_enable {
    * 0-17 * * * 0;
    * 18-21 * * * 1;
    * 22-23 * * * 0;
};

schedule temp_lock_status {
    * 18 * * * 0;
    * 19-20 * * * 1;
    * 21 * * * 0;
};

object load {
    ....;
    enable_lock temp_lock_enable;
    lock_STATUS temp_lock_status;
    ....;
}
```

Frequency controller and voltage controller respond to frequency and voltage changes within a deadband to decide whether to bring up or shut down the load. These two controllers can

be enabled by specifying **enable_freq** and **enable_volt** to be true. The deadband is specified by **freq_lowlimit,freq_uplimit** and **volt_lowlimit,volt_uplimit**. Frequency controller requires an external frequency player to feed the frequency to the system. Voltage controller can access the voltage line directly in the system.

Additionally, we also bring the "jitter function" to these two controllers where the control of ON/OFF is delayed for a random period of time. This can be specified using a variable **average_delay_time**. By default, it is set to be 0, meaning no delay is needed and the controller will respond to frequency/voltage immediately. If we want the start of GridBallast event (supposed ON/OFF status due to freq/volt violation) to delay randomly with an expected value of 60 seconds (1 min), we can set this value to 60.

```
object load_freq {
    ....;
    enable_freq_control true;
    freq_lowlimit 59.96;
    freq_uplimit 60.04;
    average_delay_time 60;
    ....;
}
```

```
object load_volt {
    ....;
    enable_volt_control true;
    volt_lowlimit 240.4;
    volt_uplimit 241.4;
    average_delay_time 60;
    ....;
}
```

Thermostat controller is optional, which is only applicable to thermostat controlled loads (TCLs, e.g., water heater). For zip load, we can ignore this controller. The variables **tank_setpoint** and **thermostat_deadbank** control the behaviour of the thermostat controller for the waterheater. If we want to disable this controller, we can set **thermostat_deadbank** to a very large value, which means the thermostat controller will never be triggered and enabled.

```
object waterheater {
    ....;
    thermostat_deadband 2.9;
    tank_setpoint 136.8;
    ....;
}
```

When we have multiple controllers, we can also adjust the priority of the order by specifying **controller_priority** variable. Recall that we have - lock mode controller [a] - frequency controller [b] - voltage controller [c] - thermostat controller [d]

By default, we are using **3214** for the waterheater and **4321** for the zipload. - The number **3214** means that the controllers are in the priority order of $d > a > b > c$. - The number **4321** means that the controllers are in the priority order of $a > b > c > d$.

```

object waterheater {
    ....;
    controller_priority 3214;
    ....;
}

```

The detailed usage of these controllers will be explained below with some simple examples.

To run this notebook, please make sure you are in a UNIX based environment and have all the necessary python packages installed (plotly, matplotlib, numpy, pandas).

```

The gridlab-d binary file is stored within **local_gd** directory along with libraries. We can check the version of the gridlabd using the following command:

```
In [2]: !local_gd/bin/gridlabd --version
```

```
GridLAB-D 4.0.0-17345 (jingkungao@JKs-MBP.local:Documen) 64-bit MACOSX RELEASE
```

The above listed **local_gd/bin/gridlabd** is the binary version of the gridlab-d software with controlling functionality. In addition to that, we have **.glm** files and generated **.csv** files. We also have a **frequency.PLAYER** containing the 1-second resolution frequency information.

The version of the gridlab-d binary file and the content of the frequency.PLAYER can be seen below.

If the version of the gridlab-d does not work, we can disable the comments below and run the command to compile the source and install the gridlab-d to the machine.

```
In [3]: # %%bash
        # cd ~
```

```

# git clone -b feature/730 https://git@github.com:INFERLab/gridlab-d.git
# cd gridlab-d
# cd third_party
# chmod +x install_xercesc
# . install_xercesc
# tar -xvf cppunit-1.12.0.tar.gz
# cd cppunit-1.12.0
# ./configure LDFLAGS="-ldl"
# make
# sudo make install
# cd ../..
# autoreconf -isf
# ./configure
# make
# sudo make install

```

In [4]: `!head -5 frequency.PLAYER`

```

2012-01-01 00:00:00 EST,59.9769
2012-01-01 00:00:01 EST,59.9763

ax.axhline(y=freq_low, c='red')
ax.axhline(y=freq_high, c='green')

```

Out[6]: <matplotlib.lines.Line2D at 0x11002ed68>

Next, we will run `local_gd/bin/gridlabd` on different `.glm` files and plot the outputs showing the difference with and without controllers.

We start with running `smSingle_base.glm`, which is almost same as the original `smSingle.glm` provided by NRECA to us with the main difference being that we changed the simulation clock and added a recorder for waterheater1 at the end.

1 Base case (one thermostat controller)

We begin with the same circuit provided by NRECA (`smSingle.glm`), and modify it slightly as follows:

- We change the simulation time to match the time of `frequency.PLAYER` and add a recorder to record the waterheater measurements and the ZIP load measurements (in this case, a fan). Note that we record data for waterheater1 as an example but it could be used for any waterheater.
- We also set the timestep to 1 second instead of 60 seconds.
- For a more realistic water draw schedule, we include a `hot_water_demand.glm` which exhibits typical the weekday and weekend water demand usage patterns.

Below we illustrate some of those changes made to the `glm` file:

```

In [7]: # from 2012-01-01 to 2012-01-02
        !head -9 smSingle_base.glm

```

```
clock {
    timezone PST+8PDT;
    starttime '2012-01-01 00:00:00';
    stoptime '2012-01-02 00:00:00';
};
```

```
#include "hot_water_demand.glm";
```

```
#set minimum_timestep=1;
```

```
In [8]: # record data for waterheater1 and fan2(zipload) at 1s resolution
        !tail -14 smSingle_base.glm
```

```
object recorder {
    interval 1;
    property base_power;
    file fan2_base.csv;
    parent fan2;
};
```

```
object recorder {
    interval 1;
    property measured_frequency,temperature,actual_load,is_waterheater_on,water_demand;
        // current_tank_status,waterheater_model,heatgain,power_state;
    file wh1_base.csv;
    parent waterheater1;
};
```

We are now ready to run a simulation with the base case (no control).

```
In [9]: # run the gridlabd.bin to start the simulation
        !local_gd/bin/gridlabd smSingle_base.glm
```

```
WARNING [INIT] : waterheater::init() : height and diameter were not specified, defaulting to 3.
```

```

Out[13]: <matplotlib.axes._subplots.AxesSubplot at 0x116fe25f8>

The above example has one thermostat controller for the water heater. For fan, there is no controller imposed, instead, a schedule is forced to the load. Moving next, we will consider adding more controllers to the base.

2 Two controllers

We first look at the case where we add one more controller to the water heater. This additional controller could be the frequency controller, voltage controller, or the lock mode controller. We start with a frequency controller with lenient frequency control.

By adding an additional controller, we assume the thermostat controller has a higher priority compared with others. In other words, we only consider letting other controllers take control if there is no thermal violation. This priority list could be changed though, as we mentioned earlier.

2.1 Lenient Frequency Control

To configure the GridBallast controller, we set specific properties of the waterheater object in the glm file. The properties corresponding to the frequency controller include:

- `enable_freq_control` [boolean]
- `freq_lowlimit` [float]
- `freq_uplimit` [float]

For this test we modify waterheater 1 and fan 2 to enable the frequency control and set a wide frequency dead-band (59.9Hz - 60.1Hz). We expect the GridBallast controller to be rarely triggered.

```
In [14]: !head -611 smSingle_lenient_freq.glm|tail -21
```

```
object waterheater {

2.3 Strict Voltage Control

We modify waterheater 1 and fan 2 to enable the voltage controller, with a band of [240.7,241.3] for the waterheater and [120.4,120.7] for the zipload. Notice in the case of voltage controller, we don't need to supply an external voltage.PLAYER file, instead, we can access the voltage line directly in the system.

WARNING [2012-01-02 00:00:00 EST] : last warning message was repeated 1 times

Now, we plot the generated waterheater data stored in **wh1_strict_volt.csv** and **fan2_strict_volt.csv** from the simulation.

```
In [28]: # We save data to wh1_strict_freq.csv and plot the results
df_strict_volt = pd.read_csv('wh1_strict_volt.csv', sep=',',
                             header=8, index_col=0, parse_dates=True,
                             infer_datetime_format=True,
                             names=['volt[V]', 'temperature[F]', 'power[kW]',
                                    'is_waterheater_on', 'water_demand[gpm]'])

df_strict_volt[['temperature[F]', 'water_demand[gpm]']].\
    plot(figsize=(12,4), secondary_y='water_demand[gpm]',
          title='[strict volt] EWH: temperature and water demand')

df_strict_volt[['temperature[F]', 'is_waterheater_on']].\
    plot(figsize=(12,4), secondary_y='is_waterheater_on',
          title='[strict volt] EWH: temperature and ON/OFF status')

df_strict_volt[['temperature[F]', 'power[kW]']].\
    plot(figsize=(12,4), secondary_y='power[kW]',
          title='[strict volt] EWH: temperature and power')
```

Out[28]: <matplotlib.axes._subplots.AxesSubplot at 0x11d9b1160>

This rapid variation of the temperature is due to the constant violation of the voltage lower limit and upper limit, and we also force the thermostat controller to have the highest priority. If we relax the voltage deadband, we will see a shape with less variance.

```
In [29]: df_strict_fan_volt = pd.read_csv('fan2_strict_volt.csv',
                                         sep=',',header=8,
                                         index_col=0,parse_dates=True,
                                         infer_datetime_format=True,
                                         names=['voltage[V]','base power[W]'])
df_strict_fan_volt['base power[W]'] = df_strict_fan_volt['base power[W]']*1000
ax = df_strict_fan_volt.plot(figsize=(12,4),secondary_y='base power[W]',
                             title='[strict volt] fan: power consumption')

# we overlay the voltage lower and upper band
volt_low = 120.4
volt_high = 120.7

ax.axhline(y=volt_low, c='red')
ax.axhline(y=volt_high, c='green')
```

Out[29]: <matplotlib.lines.Line2D at 0x1142a9c50>

As we can see, when the voltage is below the lower limit, the load is forced to be OFF during that period of time. However, when the voltage is higher than the upper limit, we cannot bring the load ON as the load is OFF according to the schedule. In other words, the normal zipload will only be able to response to low voltage event by shutting down the load.

```
In [30]: # we can plot the voltage and the lower/upper limit for the waterheater as well
volt_low = 240.7
volt_high = 241.3

ax = df_strict_volt['volt[V]'].plot(figsize=(12,4),rot=30,
                                   title='[strict volt] waterheater: voltage')
ax.axhline(y=volt_low, c='red')
ax.axhline(y=volt_high, c='green')
```

Out [30]: <matplotlib.lines.Line2D at 0x11751bb38>

2.4 Strict Frequency Control with Jitter (1 min)

We now modify the previous case (with a tight frequency deadband) and add a jitter to the response of the waterheater and fan, such that the start of GridBallast event will delay randomly with an expected value of 60 seconds (1 min). This can be done by specifying a property called **average_delay_time**. Internally, the controller delay follows a uniform distribution over the interval $[1, 2 \times \text{average_delay_time}]$.

We use 60 seconds to clearly illustrate the difference in the power consumption patterns of the water heater previously illustrated and this one with jitter control enabled. Needless to say, users can set these values differently depending on how many water heaters are connected to the network or other considerations.

```

```

```
Out[37]: <matplotlib.axes._subplots.AxesSubplot at 0x112c752b0>
```

As is seen, after applying the jitter, it tends to correct the power trace from strict frequency control case to the base case. It is obvious for the zipload[*fan*] case. Let's try the jitter with longer duration to see the same trend for the waterheater.

2.5 Strict Frequency Control with Jitter (10 mins)

We now modify the jitter such that the start of GridBallast event will delay randomly with an expected value of 600 seconds (10 mins) so that we can clearly see the jitter effects in the electric water heater as well.

```

As we can see, after applying the 10 min jitter, now the water heater is engaged less often than in the previous experiment without jitter.

As we did in previous examples, we now look into a shorter duration to better understand the effect of the jitter.

```
In [43]: # we look at jitter for the electric water heater in shorter duration
# As we can see, they behave slightly different, the one with jitter behaves
# more like the one without frequency control (base case)
df_base.iloc[80000:100000][['temperature[F]',
                             'power[kW]']].plot(figsize=(12,4),

Out[44]: <matplotlib.axes._subplots.AxesSubplot at 0x1159012e8>
```

We can apply the same jitter to the voltage controller as well. We will skip those examples. In addition to that, we can also add a lock mode controller, which we will demonstrate in the three controllers case.

3 Three Controllers

In addition to the thermostat controllers, we can add two more controllers to the waterheater, here we show how we can add frequency controller and lock mode controller. `## Lenient Frequency Control & Lock Mode Enabled`

Noticed by adding two more controllers, we assume the following priority list by default: - waterheater: thermostat controller > lock mode controller > frequency controller - zipload: lock mode controller > frequency controller

This list could be changed later by feeding an additional parameter, which we will explain in the four controllers case.

We will use a very simple example to demonstrate how to enable the lock for ON/OFF during certain period. For example, if we want to enable lock between 18:00-22:00, and force load ON between 19:00-21:00, and force load OFF between from 18:00-19:00 and 21:00-22:00, we can specify a schedule file like this.

```
In [45]: cat lock_mode_schedule.glm
```

```
schedule temp_lock_enable {
    * 0-17 * * * 0;
    * 18-21 * * * 1;
    * 22-23 * * * 0;
};

schedule temp_lock_status {
    * 18 * * * 0;
    * 19-20 * * * 1;
    * 21 * * * 0;
};
```

```
In [46]: # we decide not to override the thermostat setpoint by letting lock_OVERRIDE_TS to be f
# we can let this variable to be true if we want a very strict control of the TCLs

WARNING [2012-01-02 00:00:00 EST] : last warning message was repeated 1 times

Now, we plot the generated waterheater data stored in **wh1_lenient_freq_lock_mode.csv** and **fan2_lenient_freq_lock_mode.csv** from the simulation.

```
In [49]: # We save data to wh1_lenient_freq.csv and plot the results
df_lenient_freq_lk = pd.read_csv('wh1_lenient_freq_lock_mode.csv', sep=',',
                                   header=8, index_col=0, parse_dates=True,
                                   infer_datetime_format=True,
                                   names=['freq[Hz]', 'temperature[F]', 'power[kW]',
                                           'is_waterheater_on', 'water_demand[gpm]'])

df_lenient_freq_lk[['temperature[F]', 'water_demand[gpm]']].\
    plot(figsize=(12,4), secondary_y='water_demand[gpm]',
          title='[lenient freq lock mode] EWH: temperature and water demand')

df_lenient_freq_lk[['temperature[F]', 'is_waterheater_on']].\
    plot(figsize=(12,4), secondary_y='is_waterheater_on',
          title='[lenient freq lock mode] EWH: temperature and ON/OFF status')

df_lenient_freq_lk[['temperature[F]', 'power[kW]']].\
    plot(figsize=(12,4), secondary_y='power[kW]',
          title='[lenient freq lock mode] EWH: temperature and power')
```

Out [49]: <matplotlib.axes._subplots.AxesSubplot at 0x128345860>

As we can see, the load is off starting from 18:00, however, due to the water usage events, the temperature set point has a higher priority, and the load is ON to maintain the temperature within the dead band.

Starting from 19:00, the load is forced ON, however, once the temperature reaches the upper band, the load is forced OFF, that is why we see the dense fluctuations between 19:00-21:00.

Starting from 21:00, the load is supposed to be OFF, however, due to the temperature setting point has a higher priority, the load is forced to be ON to maintain the proper temperature.

Now let's look at the fan.

```
In [50]: df_lenient_fan_lk = pd.read_csv('fan2_lenient_freq_lock_mode.csv',
    sep=',',header=8,
    index_col=0,parse_dates=True,
    infer_datetime_format=True,
    names=['base power[W]'])
df_lenient_fan_lk = df_lenient_fan_lk*1000
df_lenient_fan_lk.plot(figsize=(12,4),
    title='[lenient freq lock mode] fan: power consumption')
```

Out [50]: <matplotlib.axes._subplots.AxesSubplot at 0x115b33c18>

The fan is quite properly behaved, it is OFF between 18:00-19:00, ON between 19:00-21:00, OFF again between 21:00-22:00. Exactly as the lock mode schedule specified. We can also look at the origin power trace for comparison.

```
In [51]: df_lenient_fan.plot(figsize=(12,4),  
title='[lenient freq] fan: power consumption')
```

Out [51]: <matplotlib.axes._subplots.AxesSubplot at 0x110a877b8>

4 Four Controllers

Now we consider the ultimate case where we have all controllers for the load. The jitters are also enabled for both frequency/voltage controllers by setting up **average_delay_time**. And we can also decide what kind of priority we want to apply to the load by specifying the variable **controller_priority**.

4.1 Normal controllers

In [52]: !head -619 smSingle_4controller_freq_volt_lock_mode.glm|tail -28

```
object waterheater {
    schedule_skew -810;
    water_demand weekday_hotwater*1;
    name waterheater1;
    parent house1;
    heating_element_capacity 4.8 kW;
    thermostat_deadband 2.9;
    location INSIDE;
    tank_volume 50;
    tank_setpoint 136.8;
    tank_UA 2.4;
    temperature 135;
    object player {
        file frequency.PLAYER;
        property measured_frequency;
    };
    enable_freq_control true;
    freq_lowlimit 59.96;
    freq_uplimit 60.04;
    heat_mode ELECTRIC;
    enable_volt_control true;
    volt_lowlimit 240.4;
    volt_uplimit 241.4;
    average_delay_time 120;
    enable_lock temp_lock_enable;
    lock_STATUS temp_lock_status;
    controller_priority 3214;
};
```

All the other properties have been explained before. For the property **controller_priority**, let's consider these four controllers: - lock mode controller [a] - frequency controller [b] - voltage controller [c] - thermostat controller [d]

The number **3214** above means that the controllers are in the priority order of $d > a > b > c$.

The number **4321** below means that the controllers are in the priority order of $a > b > c > d$.

In [53]: !head -771 smSingle_4controller_freq_volt_lock_mode.glm|tail -25

```
name fan2;
parent house2;

4.2 Abnormal controllers

To show how the priority list matters for the controller, we consider the following abnormal examples where we change **controller_priority** to 4321, which means

lock controller > freq controller > volt controller > thermostat controller

In [60]: !head -619 smSingle_4controller_freq_volt_lock_mode_abnormal.glm|tail -28

```
object waterheater {
    schedule_skew -810;
    water_demand weekday_hotwater*1;
    name waterheater1;
    parent house1;
    heating_element_capacity 4.8 kW;
    thermostat_deadband 2.9;
    location INSIDE;
    tank_volume 50;
    tank_setpoint 136.8;
    tank_UA 2.4;
    temperature 135;
    object player {
        file frequency.PLAYER;
        property measured_frequency;
```

```

};
    enable_freq_control true;
    freq_lowlimit 59.96;
    freq_uplimit 60.04;

```

Even though we remain the rest parameters the same, we can see the simulation gives abnormal results during 19:00-22:00. This is due to the lock mode controller overrides the thermostat controller and force the load to be ON. Normally we would suggest to put the thermostat controller to the highest priority (set 4 to the last digit of the four-digit integer for controller_priority). If people want to change the priority of the controllers, please make sure to be aware of the possible consequences.
